## Understanding Electric Charge

Before we dive into the specifics of electric force, it's important to understand electric charge, as it serves as the foundation for this concept. Electric charge is a fundamental property of matter, and it exists in two types: positive and negative. Protons carry a positive charge, while electrons carry a negative charge. The interaction between these charged particles gives rise to electric forces.

Electric charge can be quantified in coulombs (C), and it is conserved, meaning the total charge in an isolated system remains constant. The movement of these charges leads to the generation of electric currents, which are essential in various applications, from powering devices to lighting up homes.

## The Nature of Electric Charge

Electric charges exhibit specific behaviors when placed near each other:

- **Like charges repel:** When two objects have the same type of charge (both positive or both negative), they push away from each other.
- **Opposite charges attract:** When a positive charge is near a negative

charge, they pull towards each other.

- **Charge quantization:** Charge exists in discrete amounts, and the smallest unit of charge is that of an electron or proton, approximately equal to  $\pm 1.6 \times 10^{-19}$  coulombs.

## Electric Force Definition

Now that we have a grasp on electric charge, we can define electric force. In physics, the electric force is the attractive or repulsive interaction between charged objects. It is a vector quantity, which means it has both magnitude and direction. The electric force depends on the amount of charge and the distance between the charges.

A central principle governing electric force is Coulomb's Law, which states that the electric force ( $F$ ) between two point charges is directly proportional to the product of the magnitudes of the charges ( $q_1$  and  $q_2$ ) and inversely proportional to the square of the distance ( $r$ ) between them. This can be expressed with the formula:

$$F = k (|q_1 q_2|) / r^2$$

Here,  $k$  represents Coulomb's constant, approximately equal to  $8.99 \times 10^9 \text{ N m}^2/\text{C}^2$ . This formula illustrates how electric force decreases with increasing distance, highlighting the significance of proximity in charge interactions.
