Geometry Import and Preparation

The process typically begins with importing your 3D CAD geometry into the SOS Physics Manager. The software supports various file formats, ensuring compatibility with most design tools. Once imported, you may need to perform some cleanup operations, such as removing small features that are not relevant to the simulation or repairing any gaps or overlaps in the geometry. This preparation is vital for creating a clean computational domain.

Defining Boundary Conditions and Loads

This is arguably the most critical step in setting up a simulation. Boundary conditions define how the model interacts with its environment. For example, in a thermal simulation, you might define a constant temperature on one surface or a heat flux entering another. In a structural analysis, you would define fixed supports or applied forces. Accurately defining these conditions is paramount; otherwise, your simulation results will be misleading.

Material Assignment

After preparing the geometry and defining boundary conditions, you'll need to assign the appropriate material properties to different parts of your model. This involves selecting materials from the built-in library or defining custom ones. The manager allows for complex material models, so you can accurately represent the behavior of your chosen substances under simulated conditions.

Meshing the Domain

With the geometry, boundary conditions, and materials defined, the next step is to discretize the computational domain into a mesh. The SOS Physics Manager offers automated meshing tools that can quickly generate a suitable mesh for many problems. However, for critical areas or complex geometries, you might need to manually refine the mesh density to capture intricate details and ensure simulation accuracy. A coarser mesh runs faster but is less accurate, while a finer mesh is more accurate but takes longer to compute.

Solver Configuration and Execution

Once the mesh is generated, you configure the solver. This involves selecting the appropriate physics module, choosing numerical schemes, and setting convergence criteria. The SOS Physics Manager often provides sensible defaults, but an experienced user will fine-tune these settings for optimal performance and accuracy. After configuration, you initiate the simulation. This can take anywhere from a few minutes to several hours or even days, depending on the complexity of the model and the available computing

resources.

Advanced Customization and Optimization

For those pushing the boundaries of simulation, the SOS Physics Manager offers extensive customization options that allow for highly specialized analyses and optimized workflows. Moving beyond standard setups unlocks deeper insights and the ability to tackle novel engineering challenges.

User-Defined Functions (UDFs)

One of the most powerful customization features is the ability to create User-Defined Functions (UDFs). UDFs allow you to implement custom physics models, material properties, or boundary conditions that are not available in the standard library. This is particularly useful for research and development or for simulating highly specialized phenomena. Writing UDFs typically involves programming in languages like C or Python, integrated seamlessly with the manager.

Troubleshooting Common Issues

Even with meticulous setup, simulations can sometimes encounter issues. Understanding common problems and how to address them can save significant time and frustration. The SOS Physics Manager, like any complex software, can present challenges that require a systematic approach to resolve.

Convergence Problems

One of the most frequent issues is the solver failing to converge, meaning it cannot reach a stable solution within the specified criteria. This can be caused by a number of factors, including an overly aggressive time step, poor mesh quality in critical areas, incorrect boundary conditions, or complex non-linearities that the solver is struggling to handle. Often, refining the mesh, reducing the time step, or adjusting solver settings can resolve these issues.

Inaccurate Results

If your simulation results do not match expectations or physical reality, it's essential to re-examine your setup. This could involve verifying material properties, ensuring boundary conditions accurately reflect the physical scenario, checking the mesh quality, and confirming that the correct solver settings have been applied. Sometimes, the issue might be with the underlying assumptions of the model itself.

Memory or Performance Issues

Large or complex simulations can consume significant memory and processing power. If you're experiencing crashes due to memory limitations or excessively long computation times, consider reducing mesh density where appropriate, simplifying the geometry, or utilizing parallel processing capabilities. Profiling the simulation can sometimes help identify bottlenecks.

Software Crashes or Errors

While rare, software crashes can occur. These might be due to bugs in the software, hardware incompatibilities, or corrupted input files. Checking system requirements, ensuring your graphics drivers are up-to-date, and verifying the integrity of your project files are good first steps. The software's error logs can often provide valuable clues for diagnosis.
